

# **Operational spatial interpolation of hourly** and daily weather data for agricultural decision support systems

D. Rosillon<sup>(1)</sup>, A. Jago<sup>(1)</sup>, J. Huart<sup>(1)</sup>,

M. Journée<sup>(2)</sup>, P. Bogaert<sup>(3)</sup>, V. Planchon<sup>(1)</sup>

Weather-based forecasting models play a major role in agricultural decision support systems (DSS) but warnings are usually computed at regional level due to a limited amount of automatic weather stations (AWS). Farmers have to refer to the nearest AWS but recommendations are not always adapted to their local situation. Data interpolation

<sup>(1)</sup> Walloon Agricultural Research Centre (CRA-W - Belgium) <sup>(2)</sup> Royal Meteorological Institute (RMI - Belgium)

<sup>(3)</sup> Université catholique de Louvain (UCLouvain – Belgium)

## **could be a solution** to estimate weather conditions in farmer's fields.

## Question

What is the best method to perform **operational spatial interpolation** of air temperature and relative humidity observations at high spatial (1 km x 1 km grid) and temporal (hourly and daily) resolution in Wallonia?

|                                      |                         | <b>N</b>  | Main results         |        |        |      |      |      |       |  |

Fig 1 - Map of Pameseb and RMI networks

## 4 explanatory variables

- Longitude, latitude, elevation (static variables)
- Gridded weather forecast 'INCA' (dynamic variable)

## *Worst case studies (examples)*

Error vs observation

#### Observations at neighboring stations

 $\rightarrow$  Sensor failure

mulLR: multilinear regression ; OK: Ordinary Kriging ; KED: Kriging with External Drift NN: Nearest Neighbor ; IDW: Inverse Distance Weighted ; NAIVE: mean of observations.

**Table 1** – Statistics of absolute prediction errors for hourly air temperature interpolation: results of leave-one-out hourly simulations on 2 years.

- (1) Kriging with elevation as external drift => the best score in all cases i.e. both for temperature and humidity and for hourly and daily steps
- Integrating weather forecast as a dynamic explanatory (2)variable does seem to improve the quality of the spatialization but this requires further studies

### Semivariogram

Fixed params by grid-search optimization (not recalibrated every hour) Best model: Linear without nugget No significant impact of fine-tuning the semivariogram

| Scenario         | mean | median |
|------------------|------|--------|
| KED-xyz-grid     | 0,62 | 0,40   |
| KED-xyz-aver-sph | 0,65 | 0,43   |
| KED-xyz-aver-lin | 0,66 | 0,44   |

**Table 2** – Comparison of optimization techniques for semivariogram parametrization: aver = average of hourly calibrated semivariograms.

## Forthcoming

What additional information to improve the interpolation?

(3) Enriching the training dataset by increasing the number of AWS (from 28 to 43) does not dramatically improve the overall performance score but the issue is subtle.

platform

## Additional data sources to explore:

- Crowd-sourced weather data (farmers' AWS) **!Outliers detection!** ullet
- Reanalysis of weather data (combination of past short-range  $\bullet$ weather forecasts with observations through data assimilation)
- Remote sensing: data from meteorological satellites lacksquare
